

1. a.  You have B rows of C units
 $B \times C = AA$
 (A long and A unit)

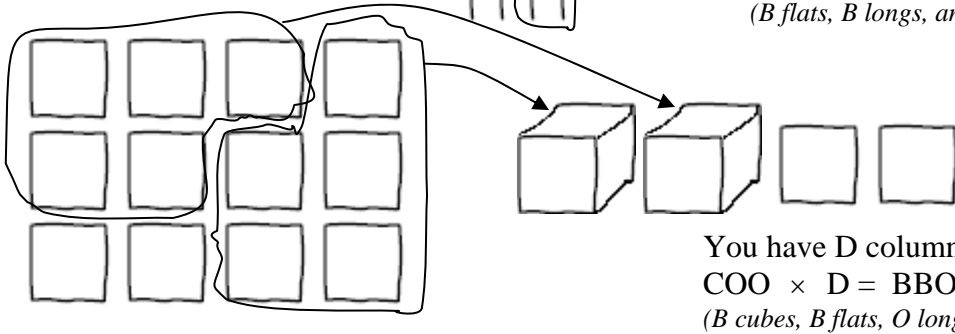

b.  You have B rows of C longs.
 $B \times CO = AAO$
 (A flat, A long, and O units)

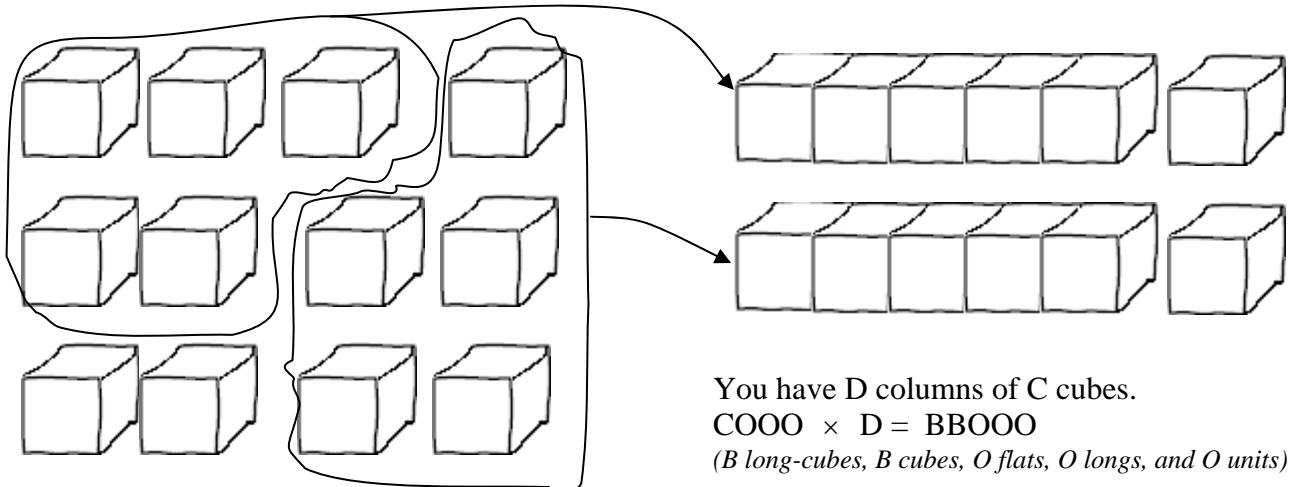

c.  You have B rows of C flats.
 $B \times COO = AAOO$
 (A cube, A flat, O longs, and O units)

 You have B rows of C cubes.
 $B \times COO = AAOOO$
 (A "long-cube", A cubes, O flats, O longs, and O units)

2. a.  You have D columns of C units
 $C \times D = BB$
 (B longs and B units)

b.  You have D columns of C longs.
 $CO \times D = BBO$
 (B flats, B longs, and O units)

c.  You have D columns of C flats.
 $COO \times D = BBOO$
 (B cubes, B flats, O longs, and O units)

d.  You have D columns of C cubes.
 $COOO \times D = BBOOO$
 (B long-cubes, B cubes, O flats, O longs, and O units)

3. a. . . .

You have A row of C units
which is already a minimal collection.
 $A \times C = C$

b. 

AO is A long and O units.
You have C longs which is already a minimal collection.
 $C \times AO = CO$
(C longs and O units)

AOO is A flat, O longs and O units.
You have C flats which is already a minimal collection.
 $C \times AOO = COO$
(C flats, O longs and O units)

AOOO is A cube, O flats, O longs and O units.
You have C cubes which is already a minimal collection.
 $C \times AOOO = COOO$
(C cubes, O flats, O longs and O units)

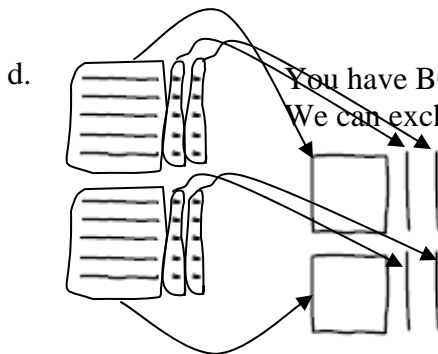

You have B rows of AB (which is A long and B units).
This makes B longs and D units which is already a minimal collection.
 $AB \times B = BD$
(B longs and D units)

You have B rows of ABO (which is A flat, B longs, and O units).
This makes B flats and D longs which is already a minimal collection.
 $ABO \times B = BDO$
(B flats, D longs and O units)

You have B rows of ABOO (which is A cube, B flats, O longs, and O units).
This makes B cubes and D flats which is already a minimal collection.
 $ABOO \times B = BDOO$
(B cubes, D flats, O longs and O units)

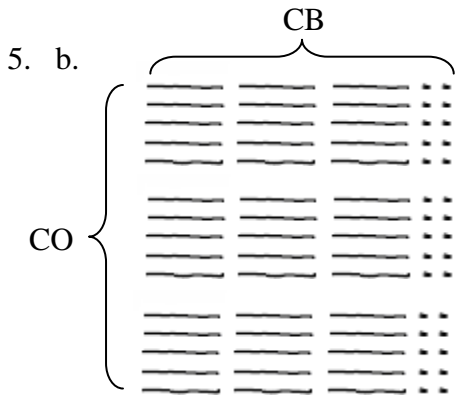

You have BO (or B hands) of AB, which is A long and B units.
We can exchange each set of AO longs for A flat, and each set of AO units for A long:

This is a minimal collection of B flats, D longs, O units or BDO.
 $AB \times BO = BDO$
Compare with 4b.

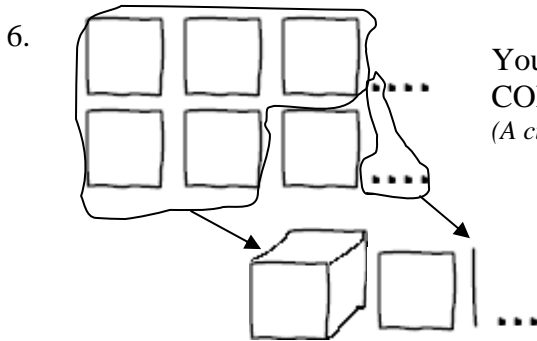

You have C rows of CB, which is C longs and B units.
Exchange hand longs for a flat, and D longs and hand units
for another flat, giving B flats, O longs, and A unit, so
 $CB \times C = BOA$

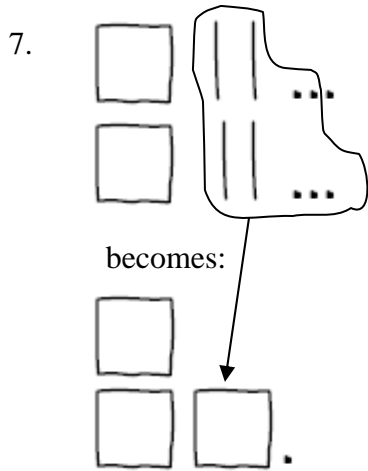

You have CO (or C hands) of CB, which is C longs and B units. We can exchange each set of AO longs for A flat, and each set of AO units for A long:

The result is B cubes, O flats, A long and O units.
 $CB \times CO = BOAO$

You have B rows of COD (which is C flats, O longs and D units).
 $COD \times B = AAAC$
(A cube, A flat, A long and C units)

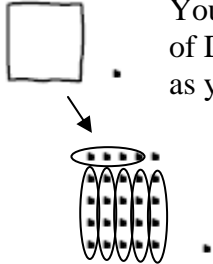

You have B rows of ABC (which is A flat, B longs, and C units). This makes C flats, O longs, and A unit after exchanges.
 $ABC \times B = COA$

You have BC, which is B longs and C units, and must take away as many groups of C as possible, so regroup the B longs into BO units. Then circle as many groups of C as you can:

Therefore you have D groups of C with A remaining, or $BC \div C = D R A$

9.  You have AOA, which is A flat, O longs and A unit, and must take away as many groups of D as possible, so regroup the A flat into AOO units. Then circle as many groups of D as you can:

Therefore you have AA groups of D with B units remaining, so $AOA \div D = AA \ R \ B$

10.  You have ACC which is A flat, C longs, and C units, and must take away as many groups of AD as you can, so regroup

becomes

which becomes

We can remove D groups which contain A long and D units, leaving AB remaining.

Therefore $ACC \div AD = D \ R \ AB$

11. To multiply by "hand", put a zero at the end.
What is $B \times AO$? It's BO and there you go.

What is $B \times CO$? It's $B \times CO$ or $B \times C \times AO$. Find $B \times C$ and multiply by hand.

$AO \times AO$ is also fun. It's AOO and then you're done.

$AOO \times AO$ is easy too. It's AOOO and then you're through.

What is $C \times BOO$? It's $(C \times B) \times AOO$, so find $C \times B$ first, then multiply by AO and AO again.

The above is modeled after *The Best of Times* by Greg Tang.

See www.gregtang.com for great books.

Recognize any properties used?

What is $COO \times BO$? Write COO as $(C \times AOO)$. Write BO as $(B \times AO)$.

$$\begin{aligned} \text{Then } COO \times BO &= (C \times AOO) \times (B \times AO) = (C \times AOO) \times (B \times AO) \\ &= (AOO \times C) \times (B \times AO) \\ &= AOO \times (C \times B) \times AO \\ &= AOO \times AO \times (C \times B) \\ &= AO \times AO \times AO \times (C \times B) \end{aligned}$$

So multiply $(C \times B)$ and then multiply by AO, then by AO, then by AO
